

Incident INC-4821

Incident Summary

Incident INC-4821 occurred on 2026-08-18 after deployment revision rel-2026.08.18. The primary symptom was elevated API latency during concurrent document-processing traffic. The first alert was recorded at 14:05 UTC and service recovery was confirmed at 14:37 UTC.

Observed Metrics

During the incident, p95 API latency increased from 420 milliseconds to 3.8 seconds. Database CPU remained below 65 percent while application event-loop utilization approached saturation. Redis latency remained within its normal operating range.

Root Cause

The root cause was event-loop contention caused by a synchronous operation executing in an asynchronous request path. The operation increased event-loop occupancy under concurrency even though PostgreSQL and Redis were not resource-saturated.

Mitigation

The immediate mitigation was to reduce concurrent processing and roll traffic back to the previous stable application revision. The service returned to the normal latency envelope after concurrency was reduced.

Incident INC-4812

Incident Summary

Incident INC-4812 affected document ingestion on 2026-08-11. Requests remained authenticated and API routing was healthy, but a subset of PDF ingestion jobs failed during embedding generation. The first alert was recorded at 09:42 UTC.

Observed Metrics

Embedding failure rate reached 18 percent for the affected workload. PDF extraction succeeded for the failed jobs, while the embedding provider returned upstream timeout responses. PostgreSQL transaction latency remained normal.

Root Cause

The root cause was upstream embedding-provider timeout behavior combined with a workload that exceeded the effective embedding concurrency budget. The application correctly rejected incomplete embedding results rather than marking partially indexed documents as ready.

Corrective Action

The corrective action was to retain bounded embedding concurrency, preserve atomic vector replacement, and measure provider latency separately from database and HTTP capacity.

Incident INC-4827

Incident Summary

Incident INC-4827 occurred during an API client migration from v1 to v2. The application remained available, but some clients received HTTP 404 responses because they continued sending requests to the retired v1 route.

Observed Metrics

The 404 response rate increased to 11 percent for the affected client population. Authenticated requests to the v2 endpoint continued to succeed. Database and Redis health metrics were normal throughout the event.

Root Cause

The root cause was an incomplete client migration. The backend was operating according to the published v2 routing contract, but one integration had not updated its API base path.

Corrective Action

The corrective action was to update the affected client, add explicit API-version compatibility checks to the integration test suite, and document the v1 retirement timeline.
